

## Transportation Logistics

# Part III: Traveling salesman problems

# Motivation

Why do we study the TSP?

- it easy to formulate
- it is a difficult problem
- many significant real-world problems can be formulated as TSP

# Application areas of the TSP

## Vehicle routing

Once the assignment of customers to routes has been done. A TSP (possibly with side constraints) has to be solved for each vehicle.

## Cutting wallpaper

Assume  $n$  sheets of wallpaper shall be cut from a single roll of paper. The amount of paper that is wasted varies depending on which sheet  $j$  is cut from the roll directly after  $i$ . We want to minimize the total wastage.

# Application areas of the TSP

## Job sequencing

$n$  jobs shall be scheduled on a single machine. The jobs can be done in any order. Assume that we have sequence dependent setup times, i.e. depending on which job  $i$  precedes job  $j$  the time needed to adapt the machine to be able to process job  $j$  varies. All jobs shall be completed in the shortest possible time.

## Clustering a data array

## Computer wiring

...

# The asymmetric TSP

$$x_{ij} = \begin{cases} 1, & \text{if arc } (ij) \text{ is part of the solution,} \\ 0, & \text{otherwise.} \end{cases}$$

$c_{ij}$  = the costs to traverse arc  $(i, j)$

$A$ ...set of arcs,  
 $V$ ...set of vertices  
 (TSP is formulated on a complete directed graph)

## IP Formulation

$$\sum_{(i,j) \in A} c_{ij} x_{ij} \rightarrow \min \quad (1)$$

$$\sum_{i \in V \setminus \{j\}} x_{ij} = 1 \quad \forall j \in V, \quad (2)$$

$$\sum_{j \in V \setminus \{i\}} x_{ij} = 1 \quad \forall i \in V, \quad (3)$$

$$\sum_{i \in S} \sum_{j \notin S} x_{ij} \geq 1 \quad \forall S \subset V, |S| \geq 2, \quad (4)$$

$$x_{ij} \in \{0, 1\} \quad \forall (i, j) \in A. \quad (5)$$

# The asymmetric TSP - connectivity/subtour elimination

Option 1 (connectivity constraints)

$$\sum_{i \in S} \sum_{j \notin S} x_{ij} \geq 1 \quad \forall S \subset V, |S| \geq 2 \quad (6)$$

Option 2 (subtour elimination constraints)

$$\sum_{i \in S} \sum_{j \in S} x_{ij} \leq |S| - 1 \quad \forall S \subset V, |S| \geq 2 \quad (7)$$

These two formulations are algebraically equivalent. They prevent the formation of subtours containing fewer than  $|S|$  vertices.

Note that the number of subtour elimination constraints needed is  $2^{|V|} - |V| - 2$ .

# The asymmetric TSP

A solution with 2 subcycles

Subtour elim. for subtour A-B-C:

Option 1:  $x_{AD} + x_{AE} + x_{BD} + x_{BE} + x_{CD} + x_{CE} \geq 1$

Option 2:

$$x_{AB} + x_{AC} + x_{BA} + x_{BC} + x_{CA} + x_{CB} (+x_{AA} + x_{BB} + x_{CC}) \leq 2$$

Subtour elim. for subtour D-E:

Option 1:  $x_{DA} + x_{EA} + x_{DB} + x_{EB} + x_{DC} + x_{EC} \geq 1$

Option 2:

$$x_{DE} + x_{ED} (+x_{DD} + x_{EE}) \leq 1$$

# A lower bound for the asymmetric TSP

The ATSP is known to be NP-hard (we do not know of a polynomial time algorithm for its solution).

A good **lower bound** on the optimal solution of the ATSP can be obtained by removing the subtour elimination constraints. The relaxed problem is the **Linear Assignment Problem!**

( $c_{ii} := \infty$  such that  $x_{ii}^* = 0$ )

**Rule:**  $z_{AP}^*$  is a good lower bound on  $z_{ATSP}^*$  if the cost matrix is strongly asymmetric. (empirical tests showed that  $(z_{ATSP}^* - z_{AP}^*)/z_{AP}^*$  often  $< 1\%$ ). If the cost matrix is symmetric,  $(z_{ATSP}^* - z_{AP}^*)/z_{AP}^*$  is often more than 30%.

Source: Laporte et al. (2004) Introduction to Logistics Systems Planning and Control, p. 252ff

# ATSP: Patching heuristic

- **Initialization**

Solve the AP. Let  $C = \{C_1, \dots, C_p\}$  denote the set of subcycles in the optimal solution of the AP. If  $|C| = 1 \rightarrow$  STOP. Otherwise proceed with step 2.

- **Step 1**

Identify the two subcycles with the largest number of vertices.

- **Step 2**

Merge these two subcycles such that the cost increase is as small as possible and update  $C$ . If  $|C| = 1 \rightarrow$  STOP. Otherwise go back to step 2.

# ATSP: Patching heuristic - Example

**Initialization** apply the Hungarian method.  
Several alternative AP solutions with  $Z = 23$ :

**Solution 1:**

$A \rightarrow C \rightarrow F \rightarrow E \rightarrow D \rightarrow B \rightarrow A$

**Solution 2:**

$A \rightarrow C \rightarrow E \rightarrow B \rightarrow A, D \rightarrow F \rightarrow D$

**Solution 3:**

$A \rightarrow C \rightarrow B \rightarrow A, D \rightarrow F \rightarrow E \rightarrow D$

...

$c_{ij}$	A	B	C	D	E	F
A	0	12	2	10	6	12
B	2	0	3	3	7	5
C	12	10	0	8	4	10
D	4	2	5	0	5	2
E	8	6	9	4	0	6
F	11	9	12	7	3	0

# ATSP: Patching heuristic - Example

$c_{ij}$	A	B	C	D	E	F
A	0	12	2	10	6	12
B	2	0	3	3	7	5
C	12	10	0	8	4	10
D	4	2	5	0	5	2
E	8	6	9	4	0	6
F	11	9	12	7	3	0

**Steps 1 and 2** Find the best way to join the two subcycles:

Insert 2nd tour between A and C:

$$A \rightarrow D \rightarrow F \rightarrow E \rightarrow C \quad \Delta = 10 + 9 - 2 - 4 = 13$$

$$A \rightarrow F \rightarrow E \rightarrow D \rightarrow C \quad \Delta = 12 + 5 - 2 - 2 = 13$$

$$A \rightarrow E \rightarrow D \rightarrow F \rightarrow C \quad \Delta = 6 + 12 - 2 - 3 = 13$$

Insert 2nd tour between C and B:

$$C \rightarrow D \rightarrow F \rightarrow E \rightarrow B \quad \Delta = 8 + 6 - 10 - 4 = 0$$

$$C \rightarrow F \rightarrow E \rightarrow D \rightarrow B \quad \Delta = 10 + 2 - 10 - 2 = 0$$

$$C \rightarrow E \rightarrow D \rightarrow F \rightarrow B \quad \Delta = 4 + 9 - 10 - 3 = 0$$

Insert 2nd tour between B and A:

$$B \rightarrow D \rightarrow F \rightarrow E \rightarrow A \quad \Delta = 3 + 8 - 2 - 4 = 5$$

$$B \rightarrow F \rightarrow E \rightarrow D \rightarrow A \quad \Delta = 5 + 4 - 2 - 2 = 5$$

$$B \rightarrow E \rightarrow D \rightarrow F \rightarrow A \quad \Delta = 7 + 11 - 2 - 3 = 13$$

e.g. best solution (several):

$$A \rightarrow C \rightarrow F \rightarrow E \rightarrow D \rightarrow B \rightarrow A$$

$$Z = 23 \text{ (upper bound on } z_{ATSP}^*)$$

# The symmetric TSP (STSP)

Since lower and upper bounding procedures for the ATSP do not perform well if applied to the STSP, procedures tailored to the STSP have been developed.

## Notation

$$x_e = \begin{cases} 1, & \text{if edge } e \text{ is part of the solution,} \\ 0, & \text{otherwise.} \end{cases}$$

$$c_e = c_{ij} = c_{ji}$$

$E$ ...edge set

## STSP: IP formulations

$$\sum_{(i,j) \in E} x_{ij} c_{ij} \rightarrow \min \quad (8)$$

$$\sum_{j \in V: (j,i) \in E} x_{ji} + \sum_{j \in V: (i,j) \in E} x_{ij} = 2 \quad \forall i \in V, \quad (9)$$

$$\sum_{(i,j) \in E: i \in S, j \notin S} x_{ij} + \sum_{(j,i) \in E: i \in S, j \notin S} x_{ji} \geq 2 \quad \forall S \subset V, 2 \leq |S| \leq \lceil |V|/2 \rceil, \quad (10)$$

$$x_e \in \{0, 1\} \quad \forall e \in E. \quad (11)$$

$i < j$  for each edge  $(i, j) \in E$

Since the connectivity constraints of subset  $S$  are equivalent to those of subset  $V \setminus S$ , we only consider  $S \subset V$  such that

$$|S| \leq \lceil |V|/2 \rceil.$$

## STSP: IP formulations

$$\sum_{e \in E} x_e c_e \rightarrow \min \quad (12)$$

$$\sum_{e \in J(i)} x_e = 2 \quad \forall i \in V, \quad (13)$$

$$\sum_{e \in E(S)} x_e \leq |S| - 1 \quad \forall S \subset V, 2 \leq |S| \leq \lceil |V|/2 \rceil \quad (14)$$

$$x_e \in \{0, 1\} \quad \forall e \in E. \quad (15)$$

$J(i)$  all edges connected to  $i$ ;  $E(S)$  edges connecting vertices in subset  $S$

## STSP: a lower bound

The STSP is also NP-hard. A valid **lower bound** on the optimal solution cost  $z_{STSP}^*$  is **the optimal solution cost of the MST**  
 $z_{MST}^*$

# STSP: Christofides' heuristic

- **Initialization** Compute a minimum spanning tree  $T$ .
- **Step 1** Compute a least-cost perfect matching among the vertices of odd degree in  $T$ . ( $V_D$ ...vertices with odd degree). Add the edges of the perfect matching ( $M$ ...vertices of the matching,  $H$ ...graph induced by union of the edges  $\in T$  and  $\in M$ ).
- **Step 2** If there is a vertex  $j \in V$  of degree  $> 2$ , eliminate two edges incident in  $j$ , denote them  $(j, k), (j, h)$  with  $k \neq h$  and add edge  $(k, h)$  (try to replace those two edges that improve the solution value the most and do not lead to subcycles). Repeat step 2 until all vertices in  $V$  have a degree of 2.

# STSP: Christofides' heuristic - Example

	O	A	B	C	D	E	T
O	0	2	4	4	8	7	13
A	2	0	2	3	6	5	11
B	4	2	0	1	4	3	9
C	4	3	1	0	5	4	10
D	8	6	4	5	0	1	5
E	7	5	3	4	1	0	6
T	13	11	9	10	5	6	0

**Initialization** compute the minimum spanning tree (Kruskal's algorithm!)

**Step 1**  $V_D = \{O, C, B, T\}$

Compute a least-cost perfect matching:

$$O - B, C - T: 4 + 10 = 14$$

$$O - C, B - T: 4 + 9 = 13$$

$$O - T, B - C: 13 + 1 = 14$$

Least cost perfect matching:

$$E(M) = \{(O, C), (B, T)\}: 4 + 9 = 13$$

**Step 2**  $j = B$  find shortcuts.

B is connected to A, C, E, T

possible shortcuts:

$$A - E: \Delta = 5 - 5 = 0$$

$$A - T: \Delta = 11 - 11 = 0$$

$$C - E: \Delta = 4 - 4 = 0$$

$$C - T: \Delta = 10 - 10 = 0$$

We choose  $C - E$

$$z_{STSP} = 27$$

$$z_{MST}^* = 14$$

# Solution methods

## Heuristic methods

- Nearest neighbor
- Cheapest insertion
- $k$ -opt (local search)

## Exact methods

- Branch and bound algorithms

## Nearest neighbor heuristic

- **Initialization** Set  $P = \{r\}$  with  $r$  being a vertex chosen arbitrarily and  $P$  denotes the (partial) TSP tour. Set  $h = r$ .
- **Step 1** Find the vertex  $k \in V \setminus P$  such that  $c_{hk} = \min_{j \in V \setminus P} \{c_{hj}\}$ . Append  $k$  to the end of  $P$ .
- **Step 2** If  $|P| = |V|$ , add  $r$  to the end of  $P$  and STOP. ( $P$  is now a Hamiltonian cycle). Otherwise, set  $h = k$  and continue with step 1.

### Hamiltonian cycle

A cycle that contains all the vertices of a graph. (TSP = problem of finding the minimum cost Hamiltonian cycle in a graph)

# Nearest neighbor heuristic - Example

	O	A	B	C	D	E	T
O	0	2	4	4	8	7	13
A	2	0	2	3	6	5	11
B	4	2	0	1	4	3	9
C	4	3	1	0	5	4	10
D	8	6	4	5	0	1	5
E	7	5	3	4	1	0	6
T	13	11	9	10	5	6	0

**Initialization**  $r = O$ ,  $P = \{O\}$ ,  $h = O$

**Step 1** identify the nearest neighbor to  $O$   
 $\rightarrow A: k = A, P = \{O, A\}, Z = 2$

**Step 2**  $|P| < |V| \rightarrow$

**Step 1** identify the nearest neighbor to  $A$   
 $\rightarrow B: k = B, P = \{O, A, B\}, Z = 4$

**Step 2**  $|P| < |V| \rightarrow$

**Step 1** identify the nearest neighbor to  $B$   
 $\rightarrow C: k = C, P = \{O, A, B, C\}, Z = 5$

**Step 2**  $|P| < |V| \rightarrow$

...

$P = \{O, A, B, C, E, D, T\}$ ,

$Z = 5 + 4 + 1 + 5 = 15$

**Step 2**  $|P| = |V|$ , append  $O$  to  $P$

$P = \{O, A, B, C, E, D, T, O\}$

$z_{TSP} = 28$

## Nearest neighbor heuristic - Observations

### Advantages

Simple and fast

### Disadvantages

Solution can be of rather poor quality. (edges added in later iterations may be quite long - especially the last edge connecting back to the first vertex)

# Cheapest insertion heuristic

- **Initialization** arbitrarily choose the first vertex  $r$ . Initialize the TSP tour  $P = \{r, r\}$ ,  $Z = 0$
- **Iteration step** If  $|P| < |V| + 1$ 
  - For each vertex  $i \in V \setminus P$  find the cheapest insertion position between any  $j$  and  $k$ ;  $j, k \in P$  and neighboring in  $P$ .
  - Find the vertex  $i^* \in V \setminus P$  that can be inserted the cheapest; insert it at its cheapest position (say  $j^*$  and  $k^*$ ):  
 $P = \{r, \dots, j^*, i^*, k^*, \dots, r\}$  and set  
 $Z = Z - c_{j^*k^*} + c_{j^*i^*} + c_{i^*k^*}$

# Cheapest insertion heuristic - Example

	O	A	B	C	D	E	T
O	0	2	4	4	8	7	13
A	2	0	2	3	6	5	11
B	4	2	0	1	4	3	9
C	4	3	1	0	5	4	10
D	8	6	4	5	0	1	5
E	7	5	3	4	1	0	6
T	13	11	9	10	5	6	0

**Initialization**  $r = O$ ,  $P = \{O, O\}$   $Z = 0$

## Iteration 1

$$O - A - O \Delta = 2 + 2 = 4$$

$$O - B - O \Delta = 4 + 4 = 8$$

$$O - C - O \Delta = 4 + 4 = 8$$

$$O - D - O \Delta = 8 + 8 = 16$$

$$O - E - O \Delta = 7 + 7 = 14$$

$$O - T - O \Delta = 13 + 13 = 26$$

$A: i^* = A$ ,  $P = \{O, A, O\}$ ,  $Z = 4$

## Iteration 2

$$O - B - A, A - B - O$$

$$\Delta = -2 + 2 + 4 = 4$$

$$O - C - A, A - C - O$$

$$\Delta = -2 + 4 + 3 = 5$$

$$O - D - A, A - D - O$$

$$\Delta = -2 + 8 + 6 = 12$$

$$O - E - A, A - E - O$$

$$\Delta = -2 + 7 + 5 = 10$$

$$O - T - A, A - T - O$$

$$\Delta = -2 + 13 + 11 = 24$$

$B: i^* = B$ ,  $P = \{O, B, A, O\}$ ,  $Z = 8$

# Cheapest insertion heuristic - Example

	O	A	B	C	D	E	T
O	0	2	4	4	8	7	13
A	2	0	2	3	6	5	11
B	4	2	0	1	4	3	9
C	4	3	1	0	5	4	10
D	8	6	4	5	0	1	5
E	7	5	3	4	1	0	6
T	13	11	9	10	5	6	0

### Iteration 3

$$O - C - B \Delta = -4 + 4 + 1 = 1$$

$$B - C - A \Delta = -2 + 1 + 3 = 2$$

$$A - C - O \Delta = -2 + 4 + 3 = 5$$

$$O - D - B \Delta = -4 + 8 + 4 = 8$$

$$B - D - A \Delta = -2 + 4 + 6 = 10$$

$$A - D - O \Delta = -2 + 8 + 6 = 12$$

...

$$C: i^* = C, P = \{O, C, B, A, O\}, Z = 9$$

...

$$P = \{O, C, T, D, E, B, A, O\}, z_{TSP} = 27$$

# Local search

## Local search

Local search algorithms are iterative procedures that try to improve an initial feasible solution  $x^{(0)}$ . At the  $k$ th iteration, all solutions contained in a 'neighborhood' of the current solution  $x^{(k)}$  are enumerated. If there exist feasible solutions that are less costly than  $x^{(k)}$ , the best solution of the neighborhood becomes the new current solution  $x^{(k+1)}$  and the procedure is repeated. Otherwise, the procedure ends. The last current solution is the **local optimum**.

Source: Laporte et al. (2004) Introduction to Logistics Systems Planning and Control, p. 263

## Neighborhood

A neighborhood is defined by all feasible solutions that can be reached by applying a given operator to a given solution (e.g.: move one vertex, exchange two vertices).

## Lin-Kernighan: $k$ -opt (local search)

- **Initialization** Let  $P^{(0)}$  be the initial TSP solution and let  $z_{TSP}^{(0)}$  be the cost of  $P^{(0)}$ . Set  $h = 0$ .
- **Step 1** Identify the best feasible solution  $P^{(h+1)}$  that can be obtained through a  $k$ -exchange. If  $z_{TSP}^{(h+1)} \geq z_{TSP}^{(h)}$ , STOP.
- **Step 2** set  $h = h + 1$  and proceed with step 1.

### $k$ -exchange

replace  $k$  links (edges) of the current solution with  $k$  new links, e.g. a 2-exchange: replace  $(i, j)$  and  $(k, l)$  by  $(i, l)$  and  $(j, k)$  (= inverse the sequence between  $j$  and  $k$ )

# Lin-Kernighan: 2-exchange

# Lin-Kernighan: 2-opt (typical picture)

16 - 50 - 9 - 49 - 30 - 34 - 21 - 29 - 2 - 11 - 32 - 1 - 22 - 38 - 31 - 8 - 25 - 7 - 23 - 48 - 27 - 51 - 46 - 12 - 47  
 - 4 - 17 - 37 - 15 - 44 - 42 - 19 - 41 - 13 - 25 - 14 - 6 - 21 - 43 - 18 - 5 - 38 - 39 - 33 - 45 - 40 - 20 - 35 - 30 - 3 - 16

 $O - C - A - B - T - D - E - O$   
 $O - A - B - T - D - E - C - O$

# Branch and bound (BB) - the concept

A general method for solving (mixed) integer optimization problems (with a minimization objective). It uses two concepts: **branching** and **bounding**.

- **Root node** solve relaxation of the optimization problem (e.g., LP of IP). Set  $LB$  to the objective function value of the relaxed problem  $z_0$  and set  $UB = \infty$ . Put the root node into the set of unprocessed nodes  $Q$ .
- **Repeat** (until  $Q$  is empty)
  - select a node  $k$  from the set  $Q$ , according to a certain criterion.
  - identify on what to **branch**
  - **branch**: partition the problem  $P_k$  at  $k$  into a given number of subproblems  $s: P_{k_1} \dots P_{k_s}$  (one child node for each subproblem); for the solution spaces wrt the original optimization problem  $L(P_k) = \cup_{i=1}^s P_{k_i}$  has to hold. (e.g., 2 child nodes: in the 1st child node (1st partition) a certain characteristic is forbidden while in the 2nd child node (2nd partition), this characteristic is enforced).
  - compute the lower bounds at the child nodes (new enforced/forbidden characteristics plus all enforced/forbidden characteristics of parent nodes); put the child nodes into  $Q$
  - **bound**: the lowest bound across all nodes  $\in Q$  gives the current  $LB$ ; a feasible solution to the original problem at a given node gives a new  $UB$ ; all open nodes associated with  $LBs \geq UB$  can be pruned (removed from  $Q$ ).

# Branch and bound (BB) - the concept

$$LB = 1011121314$$

$$UB = \infty 1614$$

# ATSP: Little et al. BB algorithm

$\theta_{ij}$  is the sum of the smallest cost element in row  $i$  (excluding  $c_{ij}$ ) and the smallest cost element in column  $j$  (excluding  $c_{ij}$ ); only computed for arcs with  $c_{ij} = 0$ .

**arc that would lead to a cycle:** e.g., already committed arcs (1,2),(3,4), new committed arc (2,3); arc that would lead to a cycle: (4,1);

e.g., already committed arcs (1,2),(3,4), new committed arc (5,6); arc that would lead to a cycle: (6,5).

# ATSP: Little et al. BB algorithm

## Lower bounds

let  $z(t)$  denote the costs of a tour under a matrix before row- and column-wise reduction (tour  $\rightarrow$  one entry in each row and column selected!); let  $z_1(t)$  denote the cost under the matrix afterward and  $h$  the reduction constant:

$$z(t) = h + z_1(t)$$

therefore,  $h$  is a valid lower bound for  $z(t)$ .

If  $c_{ij}$  is set to  $M$  (forbidden), row  $i$  and column  $j$  can be reduced by their smallest entries; the sum of these two is given by  $\theta_{ij}$ .

## ATSP: Little et al. BB - Example

Root node  $k = 0$ 

	1	2	3	4	5	6	
1	M	7	4	2	1	3	-1
2	3	M	3	2	4	6	-2
3	2	3	M	4	5	3	-2
4	7	1	5	M	4	4	-1
5	4	4	3	5	M	3	-3
6	4	3	3	6	2	M	-2

## ATSP: Little et al. BB - Example

Root node  $k = 0$ 

	1	2	3	4	5	6
1	M	6	3	1	0 (1)	2
2	1	M	1	0 (2)	2	4
3	0 (2)	1	M	2	3	1
4	6	0 (4)	4	M	3	3
5	1	1	0 (1)	2	M	0(1)
6	2	1	1	4	0 (1)	M

reduction constant =  $1+2+2+1+3+2=11$  $C_0 = 11$ 

branch on (4, 2)

## ATSP: Little et al. BB - Example

# ATSP: Little et al. BB - Example

## Compute bound at node 2

(4,2) has to be included (eliminate according row and column and set  $c_{2,4} = M$ )

	1	3	4	5	6	
1	M	3	1	0	2

# ATSP: Carpaneto-Toth BB algorithm

## Notation

- $k$  . . . node in the BB tree
- $E_k$  . . . set of excluded arcs
- $I_k$  . . . set of included arcs
- $Q$  . . . queue of unprocessed nodes

# ATSP: Carpaneto-Toth BB algorithm

a slightly simplified version

- ① **relaxation (lower bound)** modified assignment problem (MAP); AP with additional constraints: excluded and included arcs.
- ② **choose a node**  $k$  from  $Q$  (the one with the smallest cost value of the associated MAP).
- ③ **branching scheme** at node  $k$  choose the subtour  $q$  with the minimum number of arcs not included in  $I_k$ .  $A_q$  is now the set of not included arcs of subtour  $q$ ,  
 $A_q = \{(i_1, f_1), (i_2, f_2), \dots, (i_v, f_v)\}$ .  $v$  child nodes are created. For each child node  $r = 1, \dots, v$  ( $v + 1 = 1$ )

$$E_{kr} = E_k \cup \{(i_r, i_{r+1})\}$$

$$I_{kr} = I_k \cup \{(i_1, i_2), \dots, (i_{r-1}, i_r)\}$$

# ATSP: Carpaneto-Toth BB - Example
